

## Embedded System Design and Modeling

## VI. Composition of State Machines

# Composition of state machines

- ▶ How to combine multiple smaller FSMs into a bigger one?
- ▶ What problems arise?
- ▶ Two types of compositions:
  1. **Spatial** composition: how are the components connected?
  2. **Temporal** composition: how do the components react in time?

# Spatial composition

**Spatial** composition = how are two components connected, how does the information flow between the components

- ▶ **Side-by-side** composition = no common inputs/outputs, no shared data
- ▶ **Cascade** composition = Outputs of one FSM are inputs to another one
- ▶ **Feedback** composition = (Some) outputs of a FSM are inputs to the same FSM, or to some other component which is in front

# Side-by-side composition

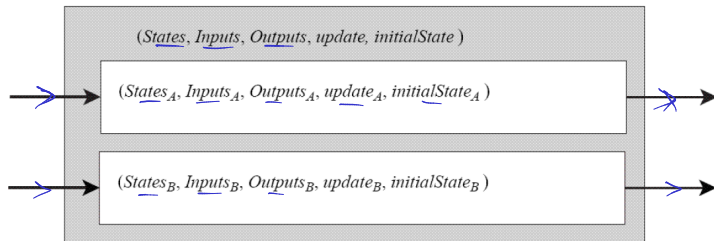

Figure 1: Side-by-side composition

# Cascade composition

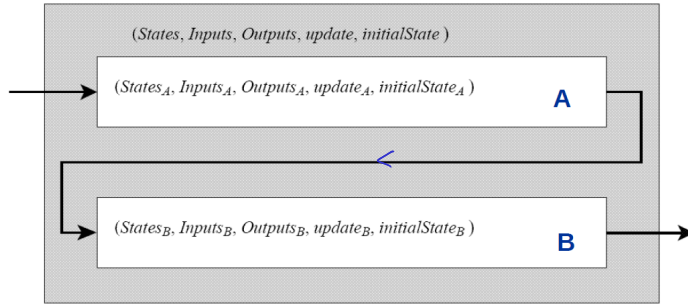

Figure 2: Cascade composition

- Outputs of FSM A are inputs to FSM B

# Feedback composition

Figure 3: Feedback composition

- Some outputs of the FSM are coming back as inputs

# Temporal composition

**Temporal** composition = when do two components react?

► Sequential vs Parallel composition:

- Sequential = the two FSM do not work at the same time
- Parallel = the two FSM work at the same time

► Asynchronous vs Synchronous composition = only for parallel composition

- Synchronous = transitions are taken at the same time in both FSMs
- Asynchronous = transitions are taken at independent times in the FSMs

time step 0.01

All FSM are driven by the same clock signal

# Sequential composition

Figure 4: Example of Sequential composition

- ▶ 13579/:<https://www.youtube.com/watch?vD3QgGpzzIM> ←
- ▶ The drone has three modes of operation, working in sequence

# Parallel composition

Figure 5: Side-by-side composition

- ▶ The two FSMs form an **equivalent model**
- ▶ When do the transitions in these FSM take place?
  - ▶ Synchronous: simultaneously
  - ▶ Asynchronous: independently

# Synchronous composition

- ▶ Consider the two FSM on the left (A and B)
- ▶ The equivalent model is on the right

$$S_C \subseteq S_A \times S_B$$

outputs:  $a, b$  (pure)

Synchronous composition

Note that these two states are not reachable.

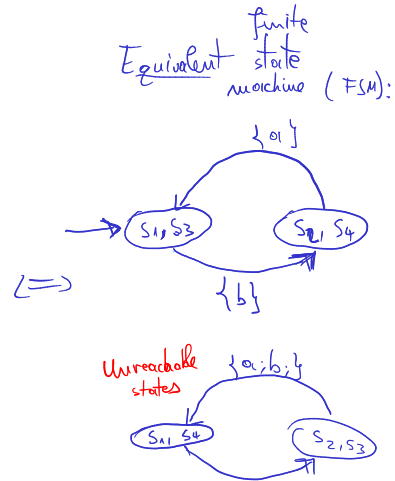

Figure 6: Synchronous composition

# Synchronous composition

See Above

Redraw here

## Synchronous composition

- ▶ In the equivalent model:
  - ▶ States = combination of states of the two FSMs
  - ▶ Transition = transition in FSM A and FSM B, happening simultaneously.
  - ▶ There might exist unreachable states in the equivalent model (states that will never be reached)

# Asynchronous composition

↑  
Transitions in A and B  
not simultaneous

Variant a).  
you never have  
trans. in A and B  
simult.

= "interleaving  
semantics"  
Draw here

b). "simultaneous  
semantics"

Equivalent FSM :

with  
simultaneous  
semantics

All states are reachable

# Asynchronous composition

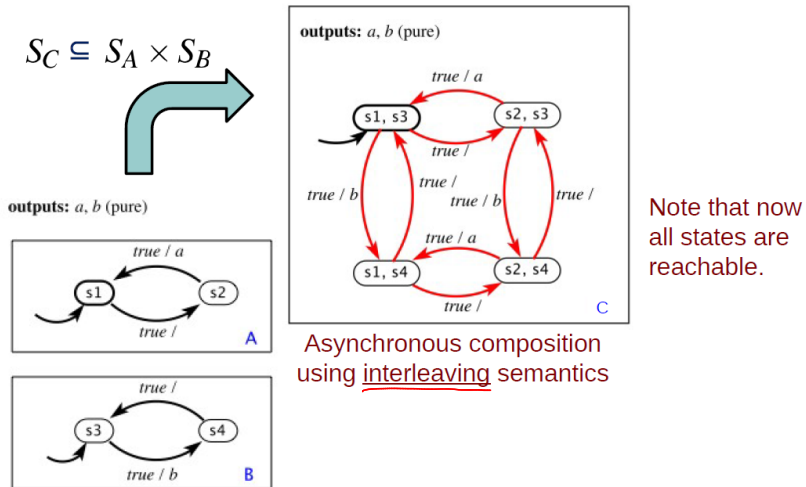

Figure 7: Asynchronous composition

# Asynchronous composition

- ▶ In the equivalent model:
  - ▶ States = combination of states of the two FSMs
  - ▶ Transitions in the two FSMs can take place at irregular and independent (not synchronized) times
  - ▶ All states are reachable
    - ▶ because one model can be much faster than the other

# Asynchronous composition

## Flavors of asynchronous composition

- ▶ How are simultaneous transitions handled?
- ▶ Interleaving semantics:
  - ▶ simultaneous transition in models A and B is not allowed (we may have either a transition in model A, or a transition in B)
  - ▶ i.e. transition from A takes place first, then transition from B takes place after a non-zero time delay (or vice-versa)
- ▶ Simultaneous semantics:
  - ▶ simultaneous transition in models A and B is allowed
  - ▶ for example, we may have either
    - ▶ transition only in model A
    - ▶ transition only in model B
    - ▶ Simultaneous transition in models A and B

you may have:

- a transition in A, not in B
- a transition in B, not in A
- a trans. in A and one in B simultaneously

## Example

- variable:**  $pcount: \{0, \dots, 55\}$   
→ **input:**  $sigR$ : pure  
→ **outputs:**  $pedG, pedR$ : pure

Pedestrian  
traffic  
light

This light stays green for 55 seconds, then goes red.  
Upon receiving a  $sigR$  input, it repeats the cycle.

Figure 8: Composition - Pedestrian Light

# Example

**variable:**  $count: \{0, \dots, 60\}$   
**inputs:**  $pedestrian: pure$   
**outputs:**  $sigR, sigG, sigY: pure$

Car  
traffic  
light

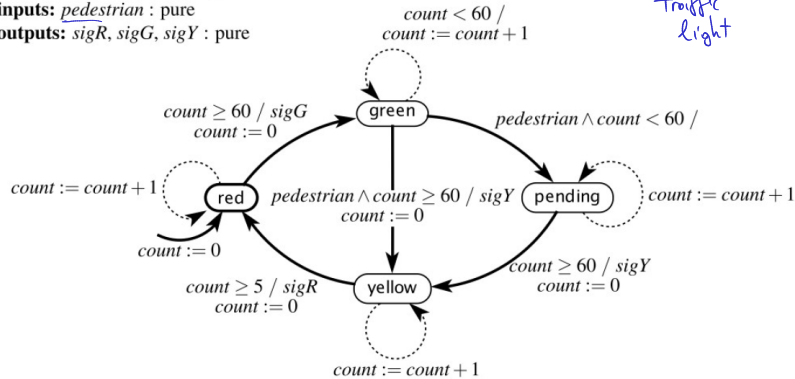

Figure 9: Composition - Car Light

# Example

## Pedestrian Light with Car Light

variable:  $count: \{0, \dots, 60\}$   
inputs:  $pedestrian: pure$   
outputs:  $sigR, sigG, sigY: pure$

sigY

sigG

sigR

What is the size of the state space of the composite machine?

sigR

variable:  $pcount: \{0, \dots, 55\}$   
input:  $sigR: pure$   
outputs:  $pedG, pedR: pure$

pedG

pedR

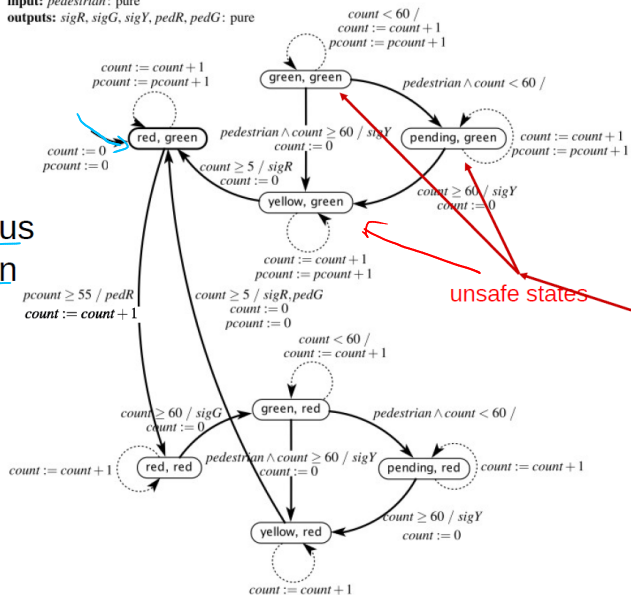

Figure 10: Cascade Composition - Both Lights

# Example

variables:  $count: \{0, \dots, 60\}, pcount: \{0, \dots, 55\}$

input:  $pedestrian: \text{pure}$

outputs:  $sigR, sigG, sigY, pedR, pedG: \text{pure}$

Synchronous  
composition

# Example

**variables:**  $count: \{0, \dots, 60\}, pcount: \{0, \dots, 55\}$

**input:**  $pedestrian: \text{pure}$

**outputs:**  $sigR, sigG, sigY, pedR, pedG: \text{pure}$

Synchronous  
composition
