

Embedded System Design and Modeling

II. Modeling of discrete systems

# Discrete dynamics

- ▶ **Dynamic system** = system whose state evolves in time
- ▶ <u>Discrete dynamics</u> = the <u>system operates</u> in a <u>sequence of discrete</u> steps
  - there are no continuous changes (no continuous signals)
  - like digital circuits (values change only on clock front)
- It's more a mathematical model (real-life is continuous), but still extremely useful

# Components of discrete signal models

- ► Systems = Actors
- ► States, Transitions, Conditions, Actions
- Properties

## Sample discrete system

#### Example of discrete system model:

Sense the cars which enter and leave a <u>parking area</u> (e.g. at barriers), and display the current number of cars inside the parking on a display.

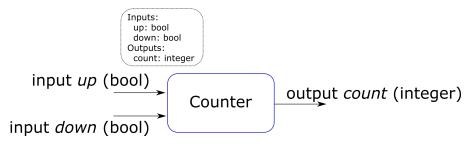

Figure 1: Parking system

### State, reaction, transitions

- ► State of the system = condition of system at a particular point in time
  - ► The state encompasses everything in the past that has any influence at the current moment
- ▶ When any input is True, the system **reacts**
- ► Reaction means that the system changes its <u>internal state</u>, and enters a new <u>state</u>
- Moving from one state to the next state means a **transition**.

## Finite State Machine representation

Finite State Machine = a system whose operation is described as a set of states and transitions

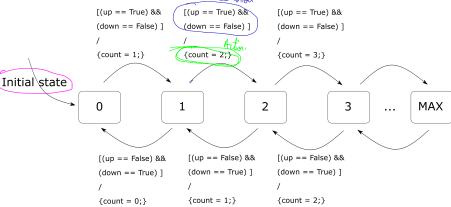

Figure 2: Parking system FSM

# Components of a FSM representation

- ► States = the "bubbles"
- ► Transitions = the arrows
- Conditions (guards) = the conditions on the transitions are taken (inside "[]")
- Actions = the instructions executed when a transition is taken(after "/", inside "{}")

### FSM notations

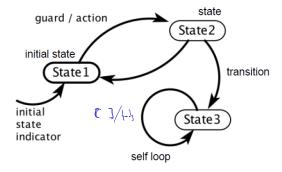

Figure 3: FSM Notations (image from Seshia slides

#### Conditions and actions

- ▶ A transition is taken when its condition becomes True
- ▶ When a transition is taken, the actions are executed
- ▶ It is possible that no transition is taken, so the system preserves its state ("default transition")
- ▶ The **initial transition** indicates which is the starting states

### FSM mathematical model

A FSM is a tuple (States, Inputs, Outputs, update) initialState) consisting of the following:

- ightharpoonup States = a set 0, 1, ...M
- ▶ Inputs = a set of variables with their data types
- Outputs = a set of variables with their data types
- ▶ update = a function  $f : States \times Inputs \rightarrow States \times Outputs$ 
  - ▶ the function takes as inputs = old state + current input values
  - ▶ the function outputs = new state + current output values
- initialState = the initial state

If all of the above is known, everything is known about the model.

### Conditions and transitions

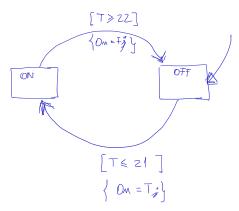

- Conditions and transitions can be written in many ways
- ► Here we use a simple C / Matlab instructions:
  - ▶ use == to check equality
  - ! means negation
  - ► True, False = boolean values
- **Examples**:
  - ▶ [a == True]
  - ▶ [!a == True]
  - >= [x >= 3]
  - ▶ [x < b]
  - etc ...

### Thermostat

 $Model\ example:\ thermostat$

### When does a reaction occur?

- ▶ When are transitions checked? (when do the reactions happen)?
- ► Two variants:
  - → Event-triggered model
  - Time-triggered model
- Event-triggered model:
  - The reaction can take time any time.
  - ▶ The environment triggers the transition, not the model
  - ► Works like an interrupt
- ► Time-triggered model:
  - ► The reaction occurs on the <u>tick</u> of an **external clock**
  - ightharpoonup e.g. everything runs at  $T_s=10$ ms, 20ms etc.

# Time-triggered models

- ► Simplest case = time-triggered models
- ► How it works:
  - ▶ the clock ticks, the FSM "wakes up"
  - the inputs are read
  - the transitions from the current state are verified
  - if a transition is true, it is executed, the system enters a new state
  - the system "goes to sleep" until the next tick

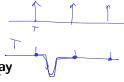

# Event vs time-triggered models

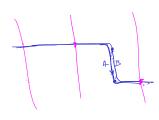

### Advantages/disadvantages of time-triggered models:

- ▶ Bad: if a input changes very fast, within a  $T_s$  interval, the model  $\underline{\mathbf{may}}$  not see it
- ► Good: all inputs are read simultaneously
- Good: simple to understand

#### Advantages/disadvantages of event-triggered models:

- ▶ Bad: the inputs are not synchronized (in a condition a > b, perhaps a changes 1ms faster than b, and this leads to a wrong result
- Good: no risk that values are lost
- ▶ Bad: difficult to analyze, difficult to understand

# Traffic light controller

Model example: car traffic light controller

[To draw]

# Properties of discrete models

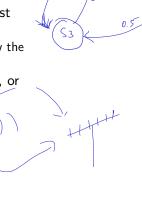

#### Properties of discrete models

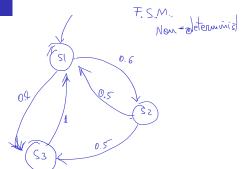

Cood

- ▶ <u>Determinism</u>: In every state, for all possible <u>input val</u>ues, at most one transition is enabled
  - if you know the initial state and all the inputs' evolution, you know the complete behavior of the system

989

Non-determinism: Models unknown behavior (unknown inputs), or random transitions

# Determinism computation tree

For a fixed input sequence and initial state:

- ► A deterministic system exhibits a single behavior
- ► A non-deterministic system exhibits a set of behaviors, visualized as a **computation tree**

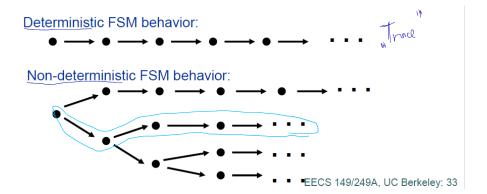

Figure 4: Computation tree (image from Seshia's slides
